

Here is a clear response and technical clarification you can provide to teams. This reply ensures your "Safety-First" logic is preserved while addressing their concerns about costs and multi-stop sequencing.

Part 1: Response to regarding UI & AI

1. UI First Approach: "Confirmed. We will finalize all UI/UX screens for the Sender, Transport Company, Driver, and Admin tiers first. This will allow us to lock in the exact user journey and 'Safety Gates' before the backend logic is built."

2. Clarification on AI vs. Internal Logic: "To clarify, what we refer to as 'AI' in the Clox blueprint is primarily our own **Proprietary Auto-Logic Decision Engine**. We agree that we should build our own logic for the following to save costs:

- **Vehicle Recommendations:** Internal code calculating the higher of Dead vs. Volumetric weight ($L \times W \times H / 4,000$).
- **Asset Allocation & Conflict Handling:** Internal logic to expire duplicate bids.
- **Base Rate Validation:** Internal database checks against Super Admin price floors.

We will only use third-party APIs for essential infrastructure that is too complex to build in-house (e.g., **Stripe** for escrow, **easyAML** for government ID checks, and **Radar.com** for traffic-aware geofencing)."

Part 2: Clarification on the "Hourly Job" (4-Hour Min)

The developer needs to understand that for local hourly work, the platform acts as a "dedicated driver for hire."

The Workflow for Hourly Jobs:

- **The 4-Hour Rule:** Senders are billed a minimum of 4 hours, even if the task takes 1 hour. This ensures compliance with the *Road Transport and Distribution Award 2020*. [1, 2]
- **The Stop Limit:** Senders can add **up to four (4) locations total** per hourly booking.
- **Flexible Sequencing:** The system must support two specific stop patterns:
 - **Pattern A (Multi-Pickup):** 3 Pickups $\rightarrow$ 1 Final Drop-off.
 - **Pattern B (Multi-Drop):** 1 Pickup $\rightarrow$ 3 Separate Drop-offs.

Challenges for the Developer to Solve (Logic Requirements):

1. **Stop Sequencing:** The system should use a basic TSP (Traveling Salesman Problem) algorithm to sequence these 4 points in the most efficient order to save the driver time.
2. **Fatigue Logic:** Even for local work, the system must check the total duration. If the auto-route planning predicts the total shift (including loading/unloading time) will exceed **5.25 hours**, the system must insert a mandatory **15-minute unpaid rest break** into the ETA and notify the sender.
3. **Wait Time Integration:** The "30-minute free pickup" and "60-minute free drop-off" rules still apply per stop. If a driver is delayed at "Stop 2" of 4, the hourly clock continues to run, but the "Detention/Waiting Charge" alerts must still trigger to notify the sender of the delay.

Summary Table for Developer Logic

Feature	Requirement	Internal Logic or API?
Stop Count	Max 4 locations (including start/end).	Internal Logic
Minimum Pay	Auto-round any local job to 4.0 hours.	Internal Logic
Route Order	Auto-sequence by shortest distance.	Internal Logic (via Google Routes)
Safety Gate	Block "Start Trip" until Mass Check at Stop 1.	Internal Logic
Fatigue Alert	Notify users if driving exceeds 5.5 hours.	Internal Logic (NHVR Standard)

Direct Instruction to Developer: "The hourly booking is designed for a dedicated truck 'for the day.' The user might pick up from 3 warehouses and drop at 1, or pick up from 1 and drop at 3 stores. The system just needs to ensure the driver doesn't exceed legal hours and that we bill the 4-hour minimum."
